Abstract

On December 13, 1994, the Securities and Exchange Commission (SEC) eliminated certain schedules that included repairs and maintenance (R&M) disclosures previously required in annual reports and registration statements filed with the SEC. The purpose of this research is to determine if market participants utilized R&M information when making investment decisions. Resulting from a variance decomposition approach, the findings indicate that market participants did use R&M disclosures in their investment decisions. Thus, as a possible policy implication of this research, the SEC may want to reconsider the decision to eliminate the required R&M expenditure disclosures.

Keywords: Repairs and Maintenance Expenses, SEC, Mandatory Disclosures, Value Relevance, Variance Decomposition.

Data Availability: All data are available from public sources.
I. Introduction

On December 13, 1994, the Securities and Exchange Commission (SEC) issued rulings 33-718, 34-35094, and IC-20766, which eliminated certain supplemental financial schedules that all foreign and domestic issuers had to include in annual reports and registration statements filed with the SEC. One of the schedules eliminated included repairs and maintenance (R&M) expenditure information. The purpose of the current study is to determine if market participants utilize R&M information when assessing the market value of a company. To date, we are aware of no research that documents the use, by market participants, of this discontinued R&M information. This lack of research represents a void in the literature that the current study seeks to fill. If the current research shows that market participants utilize R&M information, it could suggest that the SEC may want to reconsider the decision to eliminate the R&M disclosures.

Some managers consider R&M expenditures to be semi-discretionary expenditures. For example, Perry and Grinaker (1995) find evidence to suggest that managers use R & M expenditures to manage earnings. More specifically, Perry and Grinaker (1995) find that R&M expenditures decrease when earnings expectations are not met and R&M expenditures increase when earnings are expected to exceed earnings estimates. Therefore, the elimination of R&M expenditure information by the SEC could reduce the transparency of financial statements and make it easier for management to manage earnings and decrease the quality of reported earnings numbers.
To test whether market participants utilized required R&M disclosures, we use a variance decomposition approach (VAR) similar to Callen and Segal (2004) to assess the contribution of the variance of each independent variable in explaining the variance of the dependent variable, without the risk of scale effects that occur when measuring the value relevance only with the explanatory power of regressions (adjusted R square). Brown et al. (1999) present evidence that scale effects in level regressions increase the adjusted R square, making between-sample comparisons problematic. In this research, we use both VAR and Campbell’s (1991) framework. As a result, we are able to decompose the firm-level stock return into expected return news, operating earnings without R&M expenses, R&M expenses, and operating cash flow information, thus allowing us to assess the importance of each one of these sources of stock return variation for the sample firms.

Using both a variance decomposition model as well as a simple conditional regression model in which we compare the adjusted R square of models with and without the R&M information, we find evidence that R&M disclosures are indeed value relevant. Consistent with our hypothesis, our results indicate R&M information explains a portion of the variance of the market value of the firm, therefore we can assert that the SEC rulings eliminate information that investors use in evaluating and assessing a firm’s future cash flows. In addition, we find that in 1995, the first year after the elimination of R&M disclosures, only 14 out of 352 firms (i.e., 4%) in our sample decided to voluntarily continue disclosing R&M expenses. Therefore it appears that, unless
firms are required to disclose R&M expenditure information, many firms will deprive market participants of information they would use to make their investment decisions.

The remainder of the paper is organized as following. In the next section, we present the motivation for the current study, the formulation of a variance decomposition model and the hypothesis. Section III describes the research design. Section IV explains the data source and the sample selection procedure. Section V provides descriptive statistics of the variables used in testing the hypothesis and presents empirical results. Section VI presents the conclusions of the study.

II. Background

Accounting scandals such as Enron and WorldCom caused the public to demand increased accountability and transparency in financial reporting. In response, Congress passed and President George W. Bush signed into law the Sarbanes-Oxley Act of 2002. The Sarbanes-Oxley Act mandated the creation of the Public Company Accounting Oversight Board (O’Sullivan 2007). The primary purpose of the Public Company Accounting Oversight Board (PCAOB) is to improve the quality of audits performed by public accounting firms (O’Sullivan 2007). Audits provide assurance that publicly traded firms present their financial statements in accordance with generally accepted accounting principles (GAAP). In addition, the SEC relies on the external auditors of publicly traded companies to ensure that the financial statements and schedules furnished by those
companies in their filings with the SEC contain all the information required by SEC regulations.

Prior to the issuance of SEC rulings 33-718, 34-35094, and IC-20766, publicly traded companies were required to disclose information regarding R&M expenses in their filings with the SEC. During the comment period prior to adoption, preparers (e.g., registrants, accounting firms, and related professional membership associations) generally supported the elimination of the disclosures (SEC 1994). However, users (e.g., financial analysts) of financial information generally were critical of eliminating such disclosures (SEC 1994). More specifically, some financial analysts believed that the cost of providing the eliminated disclosures was small and therefore the benefits of disclosure exceeded the cost. Furthermore, they suggested that the elimination of such disclosures could result in an increase in the cost of capital due to increased investor uncertainty (SEC 1994). In spite of the comments by some financial information users, and in the interest of reducing the costs incurred by registrants, the SEC adopted rules that eliminated disclosure of R&M expenditure information. While the SEC considered comments from both preparers and users of financial information before deciding to eliminate these disclosures, they did not undertake any formal research to determine whether these disclosures were used by financial statement readers. The current study seeks to empirically determine if R&M expenditure information is used by market participants when making investments decisions.
A potential problem with eliminating R&M disclosures is that R&M expenditures may be used to manage earnings. That is, some managers may consider R&M expenditures to be semi-discretionary and therefore use R&M expenditure decisions as a way to manage earnings. For example, managers can defer R&M expenditures in years when earnings might fall short of expectations. Conversely, management can increase R&M expenditures in years when earnings may exceed expectations. Without requirements to disclose R&M expenditures, it is difficult to assess if managers engage in this type of earnings management behavior.

*Earnings Management: Manipulation of Accruals and Operating Decisions*

Literature related to earnings management is plentiful. Roychowdhury (2004) draws a distinction between two methods of managing earnings: pure accrual manipulation and real activities manipulation. *Pure accrual manipulation* is the use of end of period accruals (e.g., bad debt expense), the delay of writing-off assets and the selection of particular accounting methods to achieve a desired impact on earnings. Roychowdhury (2004) notes that pure accrual manipulations are a convenient way to manage earnings because they (1) have no direct cash flow implications, (2) can be done at the end of the period when managers are more informed about “pre-managed earnings,” and (3) can be done after “earnings targets” are known. *Real activities manipulation* is when earnings are managed by changes made to operational activities. Real activities manipulation must be done during the year before pre-managed earnings are
known and before earnings targets are known. In a commentary on earnings management, Schipper (1989) notes the difficulty of determining the extent of earnings management via real activities manipulation. Real activities manipulations that are undertaken to maximize share value are difficult to discern from those undertaken to manage earnings (Schipper 1989).

Several studies examine the use of specific accruals or specific accounting methods to manage earnings (Healy and Wahlen 1999). For example, Tech, Wong and Rao (1998) find that firms engaged in initial public offerings are more likely to use income-increasing depreciation policies and bad debt provisions. Beaver et al. (1989), Moyer (1990), Scholes et al. (1990), Wahlen (1994), Beatty et al. (1995), Collins et al. (1995) Beaver and Engel (1996), Liu and Ryan (1995) and Liu et al. (1997) all investigate bank loan loss provisions. According to Healy and Wahlen (1999), these studies find evidence of earnings management among banks. Petroni (1992) finds evidence of earnings management among insurers via property-casualty insurance claim loss reserves. Together, the foregoing studies provide convincing evidence that pure accrual manipulations are used to manage earnings.

Whereas pure accrual manipulations can be done at the end of the accounting period and do not affect cash flows, real activities manipulations must be done during the year and typically impact both cash flows and accruals (Roychowdhury 2004). In an investigation of earnings management via real activities manipulations, Roychowdhury (2006) concentrates on (1) the management of sales via “limited-time” price discounts, (2) the reduction of
discretionary expenses including advertising expenses, research and development expenses, and selling and administrative expenses, and (3) the overproduction of inventory by manufacturing firms to reduce the cost per unit of inventory. Roychowdhury (2006) finds evidence consistent with the supposition that managers manipulate sales, discretionary expenses and production levels to avoid reporting annual loses. Roychowdhury (2006) also finds evidence (although less robust) that managers manipulate real activities to meet analyst forecasts.

Using R&M expenditures to manage earnings is real operating decision and Perry and Grinaker (1995) find evidence that managers make R&M decisions in light of earnings expectations. Perry and Grinaker (1995) manually gather R&M expenditure data from Schedule X, Supplemental Income Statement Information, Form 10-K filed with the SEC from 196 U.S. firms for the period 1975-1990. Using a random walk model applied to reported earnings before income taxes and R&M expense, the authors model unexpected earnings and use a contingency table to analyze adjustments to R&M in response to positive and negative unexpected earnings. To examine the linear relationship between earnings expectations and R&M expenditures, they use Ordinary Least Squares regression.

Consequently, they find that R&M expenditures decrease when earnings expectations are not met and R&M expenditures increase when earnings exceed earnings estimates, suggesting that managers use R&M expenditures to manipulate earnings. In light of the findings by Perry and Grinaker (1995), the
elimination of R&M expenditure information by the SEC may allow managers to manipulate earnings more easily via R&M expenditures – resulting in less financial reporting transparency.

_Earnings Management and Financial Reporting Transparency_

With demands for more transparency in financial reporting, the SEC’s decision to eliminate R&M disclosures is curious. Do managers adjust their earnings management behavior based on the level of financial reporting transparency? Hunton, Libby and Mazza (2006) conduct an experiment to determine whether greater transparency in financial reporting reduces the likelihood of earnings management. They ask 62 financial executives and chief executive officers to decide which “available-for-sale” securities to sell from a portfolio. The authors utilize a 2 X 2 between subjects design manipulating the transparency of comprehensive income reporting and the relationship of projected earnings to the consensus forecast.

Hunton et al. (2006) find that comprehensive income information provided in a more transparent format (i.e., separate statement of comprehensive income) significantly reduced both income-increasing and income-decreasing earnings management behavior relative to comprehensive income information provided in a less transparent format (i.e., as part of the statement of stockholders’ equity). Furthermore, in a debriefing questionnaire, participants indicated that earnings management (1) is much more obvious when transparent reporting methods are used compared to less transparent reporting methods, (2) is likely to result in a
positive effect on stock price under less transparent reporting conditions and a negative effect under more transparent reporting, and (3) will not have an impact on reporting reputation under less transparent reporting but will have a negative effect under more transparent reporting.

The results of the Hunton et al. (2006) study suggest that financial reporting transparency influences both earnings management behavior and the perceived benefits of earnings management. Their findings further suggest that the elimination of R&M type expenditure disclosures will reduce financial reporting transparency and possibly result in an increase in earnings management via manipulation of R&M expenditures. Therefore, the elimination of R&M disclosures will make it more difficult for users of financial statements to assess the level of earnings management and will reduce the quality of reported earnings.

These studies by Roychowdhury (2004 and 2006) and Perry and Grinaker (1995) are important because they illustrate that managers can and sometimes do manage earnings via operational decisions. Furthermore, Perry and Grinaker (1995) find evidence that managers specifically use R&M expenditures to manage earnings. The research of Hunton et al. (2006) indicates that the level of financial reporting transparency impacts both earnings management behavior and the perceived benefits of earnings management. The elimination of R&M type expenditure disclosures may enable managers to manage earnings because the users of the financial statements will not able to assess the extent to
which earnings may have been manipulated by R&M expenditures. That is, the elimination of R&M disclosures makes the financial statements less transparent.

However, prior research has not determined if investors actually use R&M expenditure information when making investment decisions. This lack of research represents a void in the literature that the current study seeks to fill. If investors do not use R&M expenditure information when making investment decisions, the elimination of these disclosures should not matter. However, if investors do use R&M expenditure information when making investment decisions, prior research suggests that managers will use the non-disclosure of R&M information to their advantage and manage earnings via R&M expenditures. The investing public, unaware of the presence of earnings management, may make sub-optimal investment decisions - potentially resulting in an inefficient allocation of resources in the capital markets.

**Earnings Usefulness**

Similar to Loudder and Behn (1995), to infer earnings usefulness we first define a model relating investor valuation to contemporaneous accounting information. Using a Bayesian framework, Lev (1989) demonstrates that the correlation between stock price revisions around earnings announcements and unexpected reported earnings is inversely related to the perceived deficiencies in
reported earnings that are adjusted for market participants. The following model is adapted from Lev (1989, 187):

\[
\frac{r_B}{\sigma(P_t - P_0, \text{ERN}_t - E(\text{ERN}_t))} = \frac{\sigma(\text{ERN}_t)}{\left(\sigma^2(\text{ERN}_t) + \sigma^2(\varepsilon_{PD})\right)^{1/2}}
\]

where

- \(r_B\) = correlation between unexpected earnings and changes in price;
- \(P\) = price of the firm at time \(t\);
- \(\text{ERN}\) = earnings of the firm at time \(t\);
- \(E\) = expectations operator;
- \(\sigma^2(\text{ERN}_t)\) = variance of "ungarbled" earnings;
- \(\sigma^2(\varepsilon_{PD})\) = variance of the adjustments made by investors for the perceived deficiencies (PD) in earnings.

The model demonstrates that if earnings management increases the perceived deficiencies in reported earnings, there should be, ceteris paribus, an inverse relation between the variance of the adjustments made to accounting earnings by investors and the strength of the correlation with stock returns.

\[
\frac{\partial r_B}{\partial \sigma^2_{PD}} < 0.
\]

As the result demonstrates, the correlation between price changes and unexpected earnings will be a decreasing function of the amount of accounting error induced by methods which recognize accruals in time periods other than that in which the expected cash flows occur. Thus, usefulness is a decreasing function of the perceived amount of accounting error in reported earnings. Since it is difficult, if not impossible, to directly measure the market's perception of the

---

1 Lev's model assumes that the market can completely correct for these deficiencies. If the market does not adequately adjust for the error induced by earnings manipulation, the correlation between returns and earnings should be even weaker than that forwarded by Lev.
accounting error in a firm's reported earnings, the second step in inferring usefulness empirically is to derive an appropriate operational proxy for the market's responsiveness to the reported earnings.

**VAR Formulation**

To develop an operational definition, we adapt the formulation employed by Callen and Segal (2004), which is based on the clean surplus relation from Feltham and Ohlson (1995 and 1996). They start with the definition of cum dividends equity return:

\[ \text{Ret}_t = \left( \frac{P_t + D_t}{P_{t-1}} \right), \text{ hence} \]

\[ \log \text{Ret}_t = \log \left( \frac{P_t + D_t}{P_{t-1}} \right) \text{ or} \]

\[ r_c^t = \log \left( \frac{P_t + D_t}{P_{t-1}} \right) \]

\[ = \log (P_t + D_t) - \log (P_{t-1}) \]

\[ = p_t - p_{t-1} + \log(1 + \exp(d_t - p_t)), \]

where

\[ r_c^t \] = log cum dividend stock return at time \( t \),

\( P_t \) = market value of equity at time \( t \),

\( D_t \) = dividends at time \( t \),

\( p_t \) = log market value of equity at time \( t \),

\( d_t \) = log dividends at time \( t \).

Campbell and Shiller (1988 and 1998) use a Taylor expansion to linearize the above equation to generate a log linear valuation equation:

\[ 2 \text{ Lowercase denotes the log of uppercase letters} \]
\[ r_i^c \equiv h + \rho p_i + (1 - \rho)d_i - p_{i-1} \quad (2) \]

where

h is a constant
\( \rho \) is a constant error approximation term.

From here, substituting (2) into (1), replacing the approximation sign with an equality, and solving forward for price, we have

\[ p_i = \frac{h}{1 - \rho} + E_i \left[ \sum_{j=0}^{\infty} \rho^j (1 - \rho)d_{i+j}r_{i+j}^c \right] \quad (3) \]

Finally, the substitution of (3) into (2) yields the Campbell (1991) equation for unexpected change in current returns:

\[ r_i^c - E_{i-1}(r_i^c) = \Delta E_i \sum_{j=0}^{\infty} \rho^j (\Delta d_{i+j}) - \Delta E_i \sum_{j=1}^{\infty} \rho^j r_{i+j}^c \quad (4) \]

**Hypothesis Development**

The clean surplus relation is defined as:

\[ BV_t = BV_{t-1} + X_t - D_t \]

where:

\( BV_t \) = book value of equity at time \( t \)
\( X_t \) = net income during time \( t \)
\( D_t \) = dividends at time \( t \)
In order to adapt the Callen and Segal (2004) proof of proposition 3 to our situation, we change the definition of acc to \( acc_t = \log \left[ 1 + \left( \frac{OX_t - C_t}{OA_{t-1}} \right) \right] \). Thus, our representation is defined as

\[
acc_t = \log \left[ 1 + \left( \frac{OX_t^{RM} - RM_t - C_t}{OA_{t-1}} \right) \right]
\]

where

\( OA_{t-1} \) = net operating assets at time \( t-1 \)

\( C_t \) = free cash flow (cash flow from operations less cash investments) during time \( t \)

\( OX_t^{RM} \) = operating earnings plus repairs and maintenance expenses during time \( t \)

\( RM_t \) = repairs and maintenance expenses during time \( t \).

Hence, the change in expected returns can be expressed as:

\[
n - E_{t-1}(n) = \Delta E_i \sum_{j=0}^{\infty} \left( ox_{t+j}^{RM} - f_{t+j} \right) - \Delta E_i \sum_{j=0}^{\infty} \left( rm_{t+j} \right) - \Delta E_i \sum_{j=0}^{\infty} \left( ocf_{t+j} \right) - \Delta E_i \sum_{j=1}^{\infty} \left( r_{t+j} \right)
\]

(5)

where

\( f_t \) = log risk free rate in period \( t \)

\( f_t = \log(1 + F_t) \)

\( F_t \) = the risk-free rate of interest in period \( t \).

\( ocf_{t+j} \) = \( C_j / OA_{t-1} \)

\( ox_{t+j}^{RM} \) = \( OX_t^{RM} / OA_{t-1} \)
\( rm_{t+j} = RM_i/OA_{t-1} \)

\( r_i = \text{the ex dividend log stock return at period } t \)

\( = \log(1 + R_i + F_i) - f_i \)

\( R_i = \text{the simple ex dividend excess stock return in period } t \)

\( \Delta \) denotes the first difference operator, \( E_t \) is the expectations operator, and \( \Delta E_t = E_t(\cdot) - E_{t-1}(\cdot) \).

We can simplify the notation of equation (5):

\[
\begin{align*}
N_{r,t} &= \sum\Delta E_t \sum(r_{t+j}) \\
N_{ox,t} &= \sum\Delta E_t \sum(o_{ox, t+j} - f_{t+j}) \\
N_{rm,t} &= \sum\Delta E_t \sum(r_{m, t+j}) \\
N_{ocf,t} &= \sum\Delta E_t \sum(o_{c, t+j}) \\
\end{align*}
\]

hence

\[
N_{r,t} = N_{ox,t} - N_{rm,t} - N_{ocf,t} - N_{r,t} \tag{6}
\]

Equation (6) can be used to implement a variance decomposition of the unexpected part of the change in market returns. If we take the variance on both sides of the equation, we find:

\[
\begin{align*}
\text{Var}(N_{total}) &= \text{Var}(N_{r,t}) + \text{Var}(N_{ox,t}) + \text{Var}(N_{rm,t}) + \text{Var}(N_{ocf,t}) - \sum \text{Cov}(N_{r,t}, N_{ox,t}) - \sum \text{Cov}(N_{r,t}, N_{rm,t}) - \sum \text{Cov}(N_{r,t}, N_{ocf,t}) - \sum \text{Cov}(N_{ox,t}, N_{rm,t}) - \sum \text{Cov}(N_{ocf,t}, N_{rm,t}) - \sum \text{Cov}(N_{r,t}, N_{ocf,t}) \tag{7}
\end{align*}
\]
We use equation (7) to assess the relative importance of the different components in driving equity returns. The higher the value of the variance (covariance) of each factor on the right hand side of equation (7), the more important the factor is in explaining the variance of unexpected returns.

The hypothesis tested (in alternative form) is:

\[ H1: \text{R&M expenditures variance explains the variance of unexpected returns} \]
\[ (i.e., \text{the } R \text{ square statistic of a panel regression of returns on accounting data (including R&M) is higher than the } R \text{ square statistic of a similar panel regression without R&M data}). \]

III. Research Design

We adopt a VAR model and Campbell’s (1991) framework to decompose the firm-level stock return into expected return news, operating earnings without R&M expenses, R&M expenses, and operating cash flow information. This research design allows us to assess the importance of each of those sources of stock return variation for the firms in the sample and avoid the problem of classic value relevance literature of comparing the adjusted R square value of different samples to assess the value relevance of an accounting item. As Brown et al. (1999) show, scale effect problems occur in level regressions, making between-sample comparisons problematic. As a sensitivity check, we compare the
adjusted R squares of OLS regressions with and without R&M. Furthermore, we compare the adjusted R square of the regression for the sample with R&M expenses (1984-1994) with the adjusted R square of the regression including the same companies for a longer period (1984-2004) without R&M as an independent variable.

IV. Data source and sample selection procedure

To perform this analysis, we manually collected R&M data from individual firm 10-K reports dated 1984 to 1994. In addition, we also collected R&M information in 1995 to determine how many companies voluntarily disclosed R&M information after those disclosures were no longer mandated by the SEC. For the other required accounting data (1984-1994) we used the Compustat database and for monthly market value information we used the Center for Research in Security Prices (CRSP) database (1984-2004). We have a total of 6,866 firm-year observations for the period 1984-2004, and 2,653 firm year observations for the limited sample including R&M expenditures (1984-1994).

Following Callen and Segal (2004), we construct the variables for this study using data from Compustat. Furthermore, financial assets, financial liabilities, operating assets, and operating liabilities are computed as in Penman (2000). Net interest income and operating income are computed as in Begley and Feltham (2002). More specifically, we use the following data items from Compustat to construct the variables used in the analysis: cash and cash equivalents (DATA1), current assets (DATA4), current liabilities (DATA5), total
assets (DATA6), long-term debt (DATA9), depreciation and amortization (DATA14), interest expense (DATA15), income tax expense (DATA16), special items (DATA17), income before extraordinary items (DATA18), preferred dividends (DATA19), investments and advancements (DATA32), debt in current liabilities (DATA34), equity earnings (DATA55), stockholders’ equity (DATA60), interest income (DATA62), preferred shares (DATA130), pretax income (DATA170), short term investments (DATA193), total liabilities (DATA181), and notes payable (DATA206).

We compute accrual earnings as \([(DATA4-\text{lagged DATA4})-(DATA1-\text{lagged DATA1})]\) - \([(DATA5-\text{lagged DATA5})-(DATA34-\text{lagged DATA34})]\) - DATA14. Cash Earnings as \([DATA18 - \text{Accrual Earnings21}]\). Net Interest Income as \([(DATA62 - DATA15) \times (1 - TAX) - DATA19 + DATA5522]\). Net Operating Earnings (OXt) as \([DATA18 - DATA17 \times (1 - TAX) - DATA19 - \text{Net Interest Earned}]\). Financial Assets as \([DATA32 + DATA193 + DATA123]\). Financial Liabilities as \([DATA9 + DATA34 + DATA130 + DATA20624]\). Operating Assets as \([DATA6 - \text{Financial Assets}]\). Operating Liabilities as \([DATA181 + DATA130 - \text{Financial Liabilities}]\). Net Operating Assets as \([\text{Operating Assets} - \text{Operating Liabilities}]\). Net Financial Assets as \([\text{Financial Assets} - \text{Financial Liabilities}]\). Book Value (BVt) as \([\text{Net Operating Assets} + \text{Net Financial Assets}]\). Free Cash Flow as \([\text{Net Operating Earnings} - \text{Change in Net Operating Assets}]\). Effective Tax Rate (TAX) as \([DATA16/DATA170]\). Return on Equity (ROE) as \([(OX_t + \text{net interest income})/BV_{t-1}]\). The risk-free rate is set equal to the annualized three months US Treasury Bill rate.
V. Empirical results

To estimate the variance decomposition model highlighted above, it is necessary to specify the dynamics of the variables included in equation (6). Following previous literature (Campbell 1991; Campbell and Ammer 1993; Callen and Segal 2004; Vuolteenaaho 2002) we adopt a log-linear vector autoregressive model (VAR).

We define \( z_{it} \), as a vector of firm-specific state variables. This vector is assumed to follow a multivariate log-linear dynamic:

\[
\begin{align*}
    z_{it} &= \Gamma z_{it-1} + \eta_{it} \\
\end{align*}
\]

where:

\( \Gamma \), the VAR transition coefficient matrix, is assumed to be constant over time and over firms;

\( \eta_{it} \), the error terms vectors, are assumed to have a variance-covariance matrix \( \Sigma \) and to be independent of all known variables at \( t-1 \).

We estimate a VAR model based on one lag each of the mean-adjusted log dividend annual excess return \( r_i \), the mean-adjusted free cash flow \( ocf_i^A \), the mean-adjusted log R&M expenses \( rm_i \), and the mean-adjusted log operating earnings plus R&M expenses \( ox_i^{RM} \).

The VAR model can be described as a system of equations (variables are mean adjusted):
\[ r_i = \alpha_1 r_{t-1} + \alpha_2 \text{ocf}^A_{t-1} + \alpha_3 \text{rm}_{t-1} + \alpha_4 \text{ox}^{-\text{RM}}_{t-1} + \eta_{1,t} \]

\[ \text{ocf}^A_{t} = \beta_1 r_{t-1} + \beta_2 \text{ocf}^A_{t-1} + \beta_3 \text{rm}_{t-1} + \beta_4 \text{ox}^{-\text{RM}}_{t-1} + \eta_{2,t} \]

\[ \text{rm}_{t} = \gamma_1 r_{t-1} + \gamma_2 \text{ocf}^A_{t-1} + \gamma_3 \text{rm}_{t-1} + \gamma_4 \text{ox}^{-\text{RM}}_{t-1} + \eta_{3,t} \]

\[ \text{ox}^{-\text{RM}}_{t} = \delta_1 r_{t-1} + \delta_2 \text{ocf}^A_{t-1} + \delta_3 \text{rm}_{t-1} + \delta_4 \text{ox}^{-\text{RM}}_{t-1} + \eta_{4,t} \]

Table 1 shows the distribution of the variables of interest for the model.

[Insert Table 1 about here]

Table 2 shows the results of the estimation of the parameters of the VAR model (one lag). The significant (two tails) parameter estimates for the variable \text{LNRM\_MEAN} imply that the past one-year log of the mean of adjusted R&M expenses is statistically significant in explaining expected returns, operating earnings plus R&M expenses, actual R&M expenses, and actual operating cash flow. Expected returns and actual cash operating cash flow are low when past R&M expenses are high. Operating earnings plus R&M and actual R&M expenses are high when R&M expenses are high.

[Insert Table 2 about here]

*Relative variance decomposition*

We can then apply equation (7) to decompose the variance of the dependent variable:

[Insert Table 3 about here]
\[ \text{Var (N_{total})} = 0.974 + 0.087 + 0.018 + 0.036 - 2(0.025) + 2(-0.016) + 2(0.000) - 2(-0.025) \]
\[ = 1.116 - 0.05 - 0.032 + 0.05 = 1.084 \]

The variance of the R&M expenses news explains \( \frac{0.0182}{1.084} \), i.e. 1.7%, of the total variance of mean-adjusted returns news. The variance of the operating earnings news explains \( \frac{0.0874}{1.084} \), i.e. 8.0%, of the total variance of mean-adjusted returns news. The variance of the free cash flow news explains \( \frac{0.0363}{1.084} \), i.e. 3.3%, of the total variance of mean-adjusted returns news. The variance of the expected-returns news explains \( \frac{0.974}{1.084} \), i.e. 89.8%, of the total variance of mean-adjusted returns news.

**Sensitivity check**

To make sure the results are not dependent on the VAR model adopted, we check our findings running a panel regression for observations between 1984 and 1994\(^3\), (the period of time when R&M expense data is available).

The model adopted is:
\[
\text{Ret}_i = \alpha + \beta \times \text{INCOMBEI}_i + \gamma \times \text{RM}_i \text{YW}_i + \delta \times \text{VWRETD}_i + \eta \times \text{MKTVALUE}_i + \epsilon_i, \quad (a)
\]

We regress returns on income before extraordinary items and tax, R&M expenses while controlling for the market returns and the size of the company.

\(^3\) Qualitative similar results are obtained running OLS regressions.
The R square of this model is 0.096 and the coefficient of the R&M variable is statistically significant at 5% level.

[Insert table IV about here]

We run the same panel regression without the R&M expenses on the whole sample (1984-2004), i.e. applying the model:

\[
\text{Ret}_i = \alpha + \beta \cdot \text{INCOMBEI}_i + \delta \cdot \text{VWRETD}_i + \eta \cdot \text{MKTVALUE}_i + \varepsilon_i, \quad (b)
\]

We find a value of the R square equal to 0.043. Finally, we run the same panel regression as under model (b) but on the limited sample (1984-1994), excluding the R&M expenses:

\[
\text{Ret}_i = \alpha + \beta \cdot \text{INCOMBEI}_i + \delta \cdot \text{VWRETD}_i + \eta \cdot \text{MKTVALUE}_i + \varepsilon_i, \quad (c)
\]

We find a value of the R square equal to 0.093. There is a significant, although small, contribution of the R&M expenses number in explaining the variation of the firms’ market returns. The R square of the OLS regression for observations between 1984 and 1994 with R&M data is the highest among the three models adopted above; i.e. a loss in explanatory power of the independent variables occurs in the model when the R&M expenses are not available to investors.

*What happened after 1994?*
Since the introduction of the new regulation that eliminated certain supplemental financial schedules, firms can voluntarily disclose their R&M costs. We analyze 1995’s 10K forms for the 352 randomly drawn firms in our sample. Out of 352 firms, only 14 decided to voluntarily disclose this accounting information (less than 4%) after the change in the regulation. Hence, it appears that this SEC change in regulation deprived not only in theory but also in practice the market participants of a value relevant piece of information that investors used when this disclosure was mandatory.

VI. Conclusion

In conclusion, this research provides evidence that SEC rulings 33-718, 34-35094, and IC-20766, which eliminated certain required supplemental financial schedules that all foreign and domestic issuers had to file with the SEC, deprive investors of value relevant information. More specifically, our results provide evidence that the SEC rulings eliminate information that investors use in evaluating and assessing a firm’s future cash flows because R&M information explains a portion of the variance of the market value of the firm. The results of this study suggest that R&M disclosures are value relevant, using both a variance decomposition model as well as a simple conditional regression model. Moreover, in 1995, the first year that the disclosure of R&M expenditures became optional, only 14 out of 352 firms in our sample (4%) decided to voluntarily disclose those expenses. Thus, it appears that most firms will only provide R&M expenditure information when it is required by the SEC. The
overall result is that the elimination of R&M expenditure information by the SEC will likely reduce the transparency of financial statements, make earnings management easier and reduce the quality of reported earnings numbers. To date, no research documents the use of R&M information by market participants. The current research, which fills a void in the literature, may lead the SEC to reconsider the decision to eliminate the R&M disclosures.
